Diagrammatic illustration

Figure: Diagrammatic illustration of Many Small Prime gcd Algorithm

$$egin{align*} \mathbf{Z}[x] & ----- & \mathbf{Z}[x] & & & & & \\ k imes \mathrm{reduce} \downarrow & & & \uparrow \& \mathrm{check} \\ & \mathbf{Z}_{p_1}[x] & \xrightarrow{\mathrm{gcd}} & \mathbf{Z}_{p_1}[x] \\ & \vdots & \vdots & \vdots \\ & \mathbf{Z}_{p_k}[x] & \xrightarrow{\mathrm{gcd}} & \mathbf{Z}_{p_k}[x] \end{array} \right\} \overset{\mathrm{C.R.T.}}{\longrightarrow} & \mathbf{Z}'_{p_1 \cdots p_k}[x]$$

 $\mathbf{Z}'_{p_1\cdots p_k}[\mathbf{x}]$ indicates that some of the p_i may have been rejected by the compatibility checks, so the product is over a subset of $p_1\cdots p_k$.

More generally

gcd could be almost any algorithm that works over the integers. But we always have these questions.

- Are there "good" reductions from R?
- ② How can we tell if R_i is good?
- 4 How many reductions should we take?
- 4 How do we combine?
- 6 How do we check the result?

For this gcd the answers are

- Are there "good" reductions from R?
- A All except (a) those that divide both leading coefficients; (b) those that divide a certain resultant
- 2 How can we tell if R_i is good?
- A Type (a) immediately, Type (b) we can't but given two different answers we know which is wrong
- How many reductions should we take?
- A The answer is given by the Landau–Mignotte Bounds, but these are often too pessimistic.
- 4 How do we combine?
- A Chinese Remainder Theorem
- 6 How do we check the result?
- A Lemma implies that, if G divides both, it is the g.c.d.

Another Application: linear equations over Q

One problem is that, even if we have linear equations over **Z**, unless the determinant is 1, the answers will be over **Q** rather than **Z**. When we were looking for a g.c.d. with coefficients c: |c| < M, we needed $\prod p_i < 2M$. What happens over **Q**?

Farey Reconstruction

```
procedure FAREY(y, N \in \mathbb{N})
    Output n, d \in \mathbf{Z} such that |n|, |d| < \sqrt{N/2} and n/d \equiv y
(mod N), or failed if none such exist.
    i := 1; a_0 := N; a_1 := v; a := 1; d := 1; b := c := 0
                 \triangleright Loop invariant: a_i = ay + bN; a_{i-1} = cy + dN;
    while a_i > \sqrt{N/2} do
        a_{i+1} = \text{rem}(a_{i-1}, a_i):
        q_i:=the corresponding quotient:
                                                    \triangleright a_{i+1} = a_{i-1} - q_i a_i
        e := c - q_i a; e' := d - q_i b;
                                                        \triangleright a_{i+1} = ef + e'g
        i := i + 1:
        (c,d) = (a,b);
        (a, b) = (e, e')
    end while
    if |a| < \sqrt{N/2} and gcd(a, N) = 1 then return (a_i, a)
    else return failed
    end if
end procedure
```

Comments

This is essentially the Euclidean algorithm on y, N; tracking the dependencies.

Correctness of this algorithm, i.e. the fact that the first $a_i < \sqrt{N/2}$ corresponds to the solution if it exists, is proved in [WGD82], using [HW79, Theorem 184].

The condition gcd(a, N) = 1 was stressed by [CE95], without which we may return meaningless results, such as (-2, 2), when trying to reconstruct 5 (mod 12).

It is possible (not well written up!) to handle the case of reconstructing $\frac{c}{d}$ where |c| < C, |d| < D (i.e. different bounds), as long as N > 2CD.

-Comments

This is essentially the Euclidean algorithm on y, N; tracking the dependencies.

Correctness of this algorithm, i.e. the fact that the first

 $a_i < \sqrt{N/2}$ corresponds to the solution if it exists, is proved in [NGCB2], using [MV97, Theorem 184]. The condition gol(a,N) = 1 was stressed by [CE96], without which we may return manipless results, such as (-2,2), when trying to reconstruct S (mod 12). It is possible from well written uply to handle the case of reconstructing $\frac{c}{2}$ where |c| < C, |d| < D (i.e. different bounds), as least N (i.e. as N).

Comments

Apparently the asymmetric ($C \neq D$) case is Theorem 5.26 in [vzGG99].

How big is the determinant |M| of an $n \times n$ matrix M?

Notation

If \mathbf{v} is a vector, then $||\mathbf{v}||_2$ (sometimes also written |v|) denotes the Euclidean norm of \mathbf{v} , $\sqrt{\sum |v_i^2|}$.

Proposition

If M is an $n \times n$ matrix with entries $\leq B$, $|M| \leq n!B^n$.

This is true because the determinant is the sum of n! summands, each the product of n elements, therefore bounded by B^n . This bound is frequently used, but we can do better.

Proposition

[Hadamard bound H_r] If M is an $n \times n$ matrix whose rows are the vectors \mathbf{v}_i , then $|M| \leq H_r = \prod ||\mathbf{v}_i||_2$, which in turn is $\leq n^{n/2}B^n$.

Much better if some rows are much larger than others.

There's also a column variant

Proposition

[Hadamard bound H_r] If M is an $n \times n$ matrix whose columns are the vectors \mathbf{v}_i , then $|M| \leq H_r = \prod ||\mathbf{v}_i||_2$, which in turn is $< n^{n/2}B^n$.

Much better if some columns are much larger than others.

Application to Linear Equations

Suppose we have $M.\mathbf{x} = \mathbf{a}$ (and assume $|M| \neq 0$). Then $x_i = \frac{D_i}{D}$ where D = |M| and D_i is the determinant of the matrix replacing the *i*-th column of M by \mathbf{a} .

Hence we can choose lots of small primes and solve the linear equations (discarding those where the determinant is zero).

Choose a bound (probably using column version if a is bigger than M), and reconstruct.

Hence the questions

- 4 Are there "good" reductions from R?
- A Yes, all primes with $|M| \neq 0 \pmod{p}$
- ② How can we tell if R_i is good?
- A $|M| \neq 0 \pmod{p}$, i.e. fairly upfront. Certainly before we reconstruct.
- 4 How many reductions should we take?
- A given by the bounds
- 4 How do we combine?
- A Farey reconstruction after C.R.T.
- 6 How do we check the result?
- A We don't need to: all primes are good (as long as $|M| \neq 0$ (mod p))

Are the bounds too great?

They certainly can be.

But [AM01] shows that, for random $n \times n$ matrices, $-\log_e(|M|/H) \approx \frac{n}{2}$, so the number of "wasted bits" $\approx \frac{3n}{4}$ on average.

What about early termination?

- Note that it's early termination by constancy of $\frac{p}{q}$ that matters: the integer will change!
- If we are reconstructing the whole of \mathbf{x} , then we can check the result. But this is a much bigger win when we are only reconstructing a few x_i , and then we have no check.

Diagrammatic illustration (2)

f is some finite algorithm of +, -, *, / (and therefore tests for division by zero), producing a single result

Figure: Diagrammatic illustration of Many Small Prime f Algorithm

 $\mathbf{Z}'_{p_1\cdots p_k}[x]$ indicates that some of the p_i may have been rejected by the compatibility checks, so the product is over a subset of $p_1\cdots p_k$.

Hence the questions

- 4 Are there "good" reductions from R?
- A Yes. On a given input, f tests a finite set z_1, \ldots, z_N for being zero. Therefore, any prime not dividing $\prod z_i$ is good.
- N.B. Some primes dividing a z_i might still be good.
 - **②** How can we tell if R_i is good?
 - A Good question.
 - 4 How many reductions should we take?
 - A Good question.
 - 4 How do we combine?
 - A C.R.T., possibly with Farey reconstruction.
 - How do we check the result?
 - A Good question.

Some primes dividing a z_i might still be good

Consider our g.c.d. example

Z
$$(mod 5)$$

 $x^8 + x^6 - 3x^4 - 3x^3 + 8x^2 + 2x - 5$ $x^8 + x^6 + 2x^4 + 2x^3 + 3x^2 + 2x$
 $3x^6 + 5x^4 - 4x^2 - 9x + 21$ $3x^6 + x^2 + x + 1$
 $-15x^4 + 3x^2 - 9$
 $15795x^2 + 30375x - 59535$ $4x^2 + 3$
 $1254542875143750x$ x
 -1654608338437500 x
 $12593338[...]7500$ x

The mod 5 calculation takes a different route but ends up with the "right" answer: constant.

So what about Gröbner bases [Arn03, IPS11]

- 4 Are there "good" reductions from R?
- A Yes, by the "finite tests" rule
- **②** How can we tell if R_i is good?
- A Good question. We can look at $\{lm(g_i)\}$ for compatibility. But we don't have an equivalent of "larger degree is bad" rule from g.c.d.
- Mow many reductions should we take?
- A No useful bounds. Just wait for the answer (over **Q**) to stabilise.
- 4 How do we combine?
- A C.R.T. with Farey reconstruction to get a monic Gröbner base over **Q**.
- Mow do we check the result?
- A Good question.
